Main Text

Table 1

```
# Table one was created manually. The following code returns the values for column N  
table(g12w12$group[g12w12$wave == 1])
```

```
##  
## 1 2  
## 581 916
```

Table 1. The control group (1) comprises persons entitled to vote in the national election and all following elections because they were 18 on the day of the national election, the treatment group (2) comprises persons entitled to vote in the state and municipal elections only because they were aged 16 or 17 on the day of the national election. N = respondents who participated in both waves 1 and 2.

```

Figure 1. Visualization of the difference-in-differences design using data from all three waves of the survey. The graph plots mean values of external efficacy after the three elections in the treatment (dark grey) and control group (black) – light grey dots represent data not used in the specific analysis. Solid lines connect observed values (dots). The dashed line illustrates the parallel trends assumption, which constructs the counterfactual (circle) from the pre-treatment value in the treatment group and the trend in the control group. The difference between counterfactual and observed value represents the treatment effect.

Appendix

The survey

Table B.1

Table B.1 was manually compiled based on the field report of the survey.

Table B.1. Overview of the three survey waves on the state elections, federal elections and local elections in Schleswig-Holstein.

Figure B.1

```

source('code/timeline.R')

g_timeline

```

Table B.2

Table B.2 was manually compiled. The following code provides the N for the # three different groups.

```

table(g123w123$group[g123w123$wave1 & g123w123$wave2 & g123w123$wave == 1])

```

```

##
##  1  2  3

```

Figure 2. Estimates of the effect of losing eligibility (left panel), regaining eligibility (middle), and temporary disenfranchisement, the net effect of losing and winning eligibility (right), on external political efficacy, democratic satisfaction, political interest, and internal efficacy. The coefficient plot shows result from DiD specifications comparing groups 1 and 2 across waves 1 and 2 (left), waves 2 and 3 (middle), and 1 and 3 (right). Models are estimated on samples of respondents who took part in both waves. Horizontal bars indicate 90% and 95% confidence intervals.

Figure B.1. Periods of birth that define group membership. The vertical lines indicate the birth dates governing eligibility and thereby define the groups. The grey rectangle represents the population whose addresses we obtained from the registration offices (citizens born between 17/11/1998-07/03/2002). Young citizens belonging to group 1, born on or before 24/09/1999, are eligible for all three elections. Young citizens belonging to group 2, born after 24/09/1999 and on or before 07/05/2011, are eligible to vote in the state and municipal elections but not the federal election. Finally, young citizens belonging to group 3, born after 07/05/2001 and on or before 06/05/2002, are eligible to vote in the municipal elections only.

```
## 581 916 403
```

Table B.2. Three groups can be formed on the basis of birthdays and the associated entitlement or non-authorisation to participate in elections taking place during the observation period: (1) Persons entitled to vote in all three elections, (2) Persons entitled to vote in land and municipal elections and (3) Persons entitled to vote in municipal elections only.

Table B.3

Table F.6 The effect of temporary disenfranchisement on turnout. Columns (1) and (2) capture results from DiD-specifications comparing groups 1 and 2 across waves 1 and 3. The model in column 1 controls for differential levels and trends in living at home and attending school between the two groups by including respective covariates. The model in column 2 controls for these factors by being estimated on a sample of voters who experience no change in values for these covariates from waves 1 to 3. Columns (3) and (4) capture results from cross-sectional specifications comparing groups 2 and 3 in wave 3. The first model is a linear model estimated by OLS, while the second model is a logistic model estimated by maximum likelihood.

Creating treatment and control groups that resemble each other more closely

Figure G.1

Below, the code for the figure is included to provide an ordered overview of all figures and tables presented in the appendix. However, it is excluded with # from the main script here because the code section is already part of the data preparation in the script data.R. This script is run in the beginning of the rmd file. You will, therefore, find the same code snipped in the data preparation file in the corresponding lines 216-271.

Figure H.2. Estimates of the effect of losing eligibility (left panel), regaining eligibility (mid panel) and both taken together, i.e., temporary disenfranchisement, (right panel) on external political efficacy, democratic satisfaction, political interest, and internal efficacy based on different samples. We estimate the DiD-specification on various samples of respondents defined by their birthdate: up to 50, 100, 150, 200, 250, or 300 days before or after the cutoff date defining eligibility in the national election. The coefficient plot shows results from DiD-specifications comparing groups 1 and 2 across waves 1 and 2 (left panel), waves 2 and 3 (middle panel), and 1 and 3 (right panel). Horizontal bars indicate 95% confidence intervals
